AUDIO CIRCUITS USING THE NE5532/33/34

The following will explain some of Philips Semiconductors low noise op amps and show their use in some audio applications.

DESCRIPTION

The 5532 is a dual high-performance low noise operational amplifier. Compared to most of the standard operational amplifiers, such as the 1458, it shows better noise performance, improved output drive capability and considerably higher small-signal and power bandwidths.

This makes the device especially suitable for application in high quality and professional audio equipment, instrumentation and control circuits, and telephone channel amplifiers. The op amp is internally-compensated for gains equal to one. If very low noise is of prime importance, it is recommended that the 5532A version be used which has guaranteed noise voltage specifications.

APPLICATIONS

The Philips Semiconductors 5532 High-Performance Op Amp is an ideal amplifier for use in high quality and professional audio equipment which requires low noise and low distortion.

The circuit included in this application note has been assembled on a PC board, and tested with actual audio input devices (Tuner and Turntable). It consists of an RIAA (Recording Industry Association of America) preamp, input buffer, 5-band equalizer, and mixer.

Although the circuit design is not new, its performance using the 5532 has been improved.

The RIAA preamp section is a standard compensation configuration with low frequency boost provided by the Magnetic cartridge and the RC network in the op amp feedback loop. Cartridge loading is accomplished via R1. 47k was chosen as a typical value, and may differ from cartridge to cartridge.

The Equalizer section consists of an input buffer, 5 active variable band pass/notch (depending on R9’s setting) filters, and an output summing amplifier. The input buffer is a standard unity gain design providing impedance matching between the preamplifier and the equalizer section. Because the 5532 is internally-compensated, no external compensation is required. The 5-band active filter section is actually five individual active filters with the same feedback design for all five. The main difference in all five stages is the values of C5 and C6, which are responsible for setting the center frequency of each stage. Linear pots are recommended for R9. To simplify use of this circuit, a component value table is provided, which lists center frequencies and their associated capacitor values. Notice that C5 equals (10) C6, and that the Value of R8 and R10 are related to R9 by a factor of 10 as well. The values listed in the table are common and easily found standard values.

RIAA EQUALIZATION AUDIO PREAMPLIFIER USING NE5532A

With the onset of new recording techniques with sophisticated playback equipment, a new breed of low noise operational amplifiers was developed to complement the state-of-the-art in audio reproduction. The first ultra-low noise op amp introduced by Philips Semiconductors was called the NE5534A. This is a single operational amplifier with less than 4nV/√Hz input noise voltage. The NE5534A is internally-compensated at a gain of three. This device has been used in many audio preamp and equalizer (active filter) applications since its introduction early last year.

Many of the amplifiers that are being designed today are DC-coupled. This means that very low frequencies (2-15Hz) are being amplified. These low frequencies are common to turntables because of rumble and tone arm resonances. Since the amplifiers can reproduce these sub-audible tones, they become quite objectionable because the speakers try to reproduce these tones. This causes non-linearities when the actual recorded material is amplified and converted to sound waves.

The RIAA has proposed a change in its standard playback response curve in order to alleviate some of the problems that were previously discussed. The changes occur primarily at the low frequency range with a slight modification to the high frequency range (See Figure 2). Note that the response peak for the bass section of the playback curve now occurs at 31.5Hz and begins to roll off below that frequency. The roll-off occurs by introducing a fourth RC network with a 7950µs time constant to the three existing networks that make up the equalization circuit. The high end of the equalization curve is extended to 20kHz, because recordings at these frequencies are achievable on many current discs.

Figure 3. RIAA Phonograph Preamplifier Using the NE5532A

NE5533/34 DESCRIPTION
the 5533/5534 are dual and single high-performance low noise operational amplifiers. Compared to other operational amplifiers, such as TL083, they show better noise performance, improved output drive capability and considerably higher small-signal and power bandwidths.

This makes the devices especially suitable for application in high quality and professional audio equipment, instrumentation and control circuits, and telephone channel amplifiers.

The op amps are internally-compensated for gain equal to, or higher than, three. The frequency response can be optimized with an external compensation capacitor for various applications (unity gain amplifier, capacitive load, slew rate, low overshoot, etc.) If very low noise is of prime importance, it is recommended that the 5533A/5534A version be used which has guaranteed noise specifications.

APPLICATIONS
Diode Protection of Input
The input leads of the device are protected from differential transients above ±0.6V by internal back-to-back diodes. Their presence imposes certain limitations on the amplifier dynamic characteristics related to closed-loop gain and slew rate.

Consider the unity gain follower as an example:

Assume a signal input square wave with dV/dt of 250V/μs and 2V peak amplitude as shown. If a 22pF compensation capacitor is inserted and the R1 C1 circuit deleted, the device slew rate falls to approximately 7V/μs. The input waveform will reach 2V/250V/μs or 8ns, while the output will have changed (8×10^-3) only 56mV. The differential input signal is then (V_{IN}-V_{O}) R_{I}/R_{I}+R_{F} or approximately 1V.

The diode limiter will definitely be active and output distortion will occur; therefore, V_{IN}<1V as indicated.

Next, a sine wave input is used with a similar circuit.

The slew rate of the input waveform now depends on frequency and the exact expression is
\[
\frac{dv}{dt} = 2\omega \cos \omega t
\]

The upper limit before slew rate distortion occurs for small-signal (V_{IN}<100mV) conditions is found by setting the slew rate to 7V/μs. That is:

\[
7 \times 10^6 \text{V/μs} = 2\omega \cos \omega t
\]

at \(\omega t = 0\)

\[
\omega_{\text{LIMIT}} = \frac{7 \times 10^6}{2} = 3.5 \times 10^6 \text{rad/s}
\]

\[
f_{\text{LIMIT}} = \frac{3.5 \times 10^6}{2\pi} \approx 560\text{kHz}
\]
External Compensation Network Improves Bandwidth

By using an external lead-lag network, the follower circuit slew rate and small-signal bandwidth can be increased. This may be useful in situations where a closed-loop gain less than 3 to 5 is indicated. A number of examples are shown in subsequent figures. The principle benefit of using the network approach is that the full slew rate and bandwidth of the device is retained, while impulse-related parameters such as damping and phase margin are controlled by choosing the appropriate circuit constants. For example, consider the following configuration:
The major problem to be overcome is poor phase margin leading to instability.

By choosing the lag network break frequency one decade below the unity gain crossover frequency (30-50MHz), the phase and gain margin are improved. An appropriate value for $R$ is $270\ \Omega$. Setting the lag network break frequency at $5MHz$, $C$ may be calculated

$$C = \frac{1}{2\pi \times (0.27) \times 5 \times 10^6}$$

$$= 118pF$$

**RULES AND EXAMPLES**

**Compensation Using Pins 5 and 8 (Limited Bandwidth and Slew Rate)**

A single-pole and zero inserted in the transfer function will give an added $45^\circ$ of phase margin, depending on the network values.

**Calculating the Lead-Lag Network**

$$C_t = \frac{1}{2\pi \times F_1 \times R_1}$$

Let $R_1 = \frac{R_{IN}}{10}$

where

$$F_1 = \frac{1}{10} (UGBW)$$

$$UGBW = 30MHz$$

**External Compensation for Wide-Band Voltage-Follower**

**Shunt Capacitance Compensation**

$$C_F = \frac{1}{2\pi \times F_F \times R_F} \quad F_F \approx 30MHz$$

or

$$C_F = \frac{C_{DIST}}{A_{CL}}$$

$C_{DIST} = $ Distributed Capacitance $= 2 - 3pF$

Many audio circuits involve carefully-tailored frequency responses. Pre-emphasis is used in all recording mediums to reduce noise and produce flat frequency response. The most often used de-emphasis curves for broadcast and home entertainment systems are shown in Figure 13. Operational amplifiers are well suited to these applications because of their high gain and easily-tailored frequency response.

**RIAA PREAMP USING THE NE5534**

The preamplifier for phono equalization is shown in Figure 14 with the theoretical and actual circuit response. Low frequency boost is provided by the inductance of the magnetic cartridge with the RC network providing the necessary break points to approximate the theoretical RIAA curve.

**RUMBLE FILTER**

Following the amplifier stage, rumble and scratch filters are often used to improve overall quality. Such a filter designed with op amps uses the 2-pole Butterworth approach and features switchable break points. With the circuit of Figure 15, any degree of filtering from fairly sharp to none at all is switch-selectable.

**TONE CONTROL**

Tone control of audio systems involves altering the flat response in order to attain more low frequencies or more high ones, dependent upon listener preference. The circuit of Figure 16 provides 20dB of bass or treble boost or cut as set by the variable resistance. The actual response of the circuit is shown also.

**BALANCE AND LOUDNESS AMPLIFIER**

Figure 17 shows a combination of balance and loudness controls. Due to the non-linearity of the human hearing system, the low frequencies must be boosted at low listening levels. Balance, level, and loudness controls provide all the listening controls to produce the desired music response.

**VOLTAGE AND CURRENT OFFSET ADJUSTMENTS**

Many IC amplifiers include the necessary pin connections to provide external offset adjustments. Many times, however, it becomes necessary to select a device not possessing external adjustments. Figures 18, 19, and 20 suggest some possible arrangements for off-circuitry. The circuitry of Figure 20 provides sufficient current into the input to cancel the bias current requirement. Although more simplified arrangements are possible, the addition of $Q2$ and $Q3$ provide a fixed current level to $Q1$, thus, bias cancellation can be provided without regard to input voltage level.
